

Buzzy Canvas Full Script

[HOOK]

Okay, so picture this. [pause] You want to make an AI video. Not just one clip an actual video, with a story, a character, maybe a few different shots that need to look like they belong together.

So what do you do? [breathe] You write the script in one app. You generate a character somewhere else. You try to get a consistent face across five different prompts and it keeps drifting. Then you're piecing storyboard frames together in your head, generating clips one at a time, hoping shot three still looks like the same person as shot one.

[pause] It's exhausting. And most of the time you just end up with a pile of disconnected clips instead of an actual video.

[long pause] So what if the entire thing script, characters, storyboard, final video lived in one workspace, and you could see and adjust every step before you ever hit generate?

That's what I've been testing this week. And it's called Buzzy Canvas.

[INTRO]

What's up, everyone. [breathe] Today we're looking at Buzzy Canvas, and the way I'd describe it is basically your entire AI video production pipeline, laid out on one visual canvas. Script. Characters. Scenes. Storyboard. Final generation. All in the same place, all connected.

In this video I'm going to walk through the full workflow end to end from a simple idea all the way to a finished video and show you exactly how each step builds on the last. [breathe] Stick around, because the storyboard step is the part that actually changes how controllable AI video generation feels. Alright, let's get into it.

[SECTION 1: The Real Problem With AI Video Creation]

Here's the thing nobody really talks about. [pause] The hard part of AI video isn't generating one good clip. Anyone can get lucky with a single prompt. The hard part is making ten clips that all look like they belong in the same video.

Same character, same face, same outfit, same lighting, same world shot after shot. [breathe] And normally, that means jumping between a script tool, an image generator for your character, another tool for scene references, and then a separate video generator, praying it all lines up.

By the time you've done that for a six-shot sequence, you've spent hours just managing consistency instead of actually making anything. [pause] That's the exact problem Buzzy

Canvas is built to solve one workspace, one continuous workflow, from idea to finished video.

[SECTION 2: Step 1 From Simple Idea to Full Script]

So let me walk through how this actually works, step by step. [breathe]

It starts with a simple idea. Just a topic, a rough concept, or a couple of lines of a script. Buzzy Canvas runs on Gemini Omni under the hood for the text and logic side, and it takes that simple prompt and expands it into a complete, structured video script scenes broken out, direction laid out, an actual production plan instead of just an idea.

[screen recording of script step] So here, I just typed in a loose concept. [pause] And look it comes back with a structured script I can actually shoot from. That's step one done, and I haven't touched a single other app yet.

[SECTION 3: Step 2 Character Concept Art & Scene Setup]

Now here's where it gets interesting. [breathe] Once the script exists, Canvas moves into building the visual foundation character concept art, character three-view references, and scene or environment setup.

This is powered by models like Nano Banana 2 and GPT Image 2, so you're getting real image-generation quality for your character designs, product visuals, and scene references not placeholder sketches.

[screen recording] Here I generated a character concept, and then a three-view reference off of it front, side, profile. [pause] Why does that matter? Because if you're making an AI short drama, a cinematic piece, or any kind of long-form storytelling video, your character has to stay recognizable from shot to shot. Without a reference like this, faces drift, outfits change, and viewers notice immediately. With it, the same character carries through the whole project.

[SECTION 4: Step 3 9-Square Storyboard Frames]

Okay, this is the part I actually want you to pay attention to. [long pause]

Once you've got your script, your character references, and your scene setup, Canvas turns all of it into a 9-square storyboard grid. Every frame in that grid can reference the same character and the same scene, so consistency carries through automatically instead of you having to force it.

[breathe] And inside each frame, you can adjust lighting to shift the mood and atmosphere. [screen recording lighting adjustment] Watch same frame, warmer light, completely different feel.

You can also adjust the camera angle per frame, to control perspective and make individual shots feel more dynamic or more cinematic. [screen recording angle adjustment] Same character, same scene, different angle, different energy.

[pause] And because it's a 9-square grid, everything is fully visualized at once. You're not guessing what shot four looks like next to shot five you can see the whole sequence, adjust any frame directly, and refine details before you've generated a single second of video. That's the controllability that most AI video tools just don't give you.

[SECTION 5: Step 4 One-Click Video Generation Sync]

So now the script is written, the characters and scenes are locked in, and the storyboard is refined frame by frame. [breathe] Last step one-click generation.

Canvas takes everything you've built script, character references, scene setup, storyboard frames and syncs it into the final video generation pass, powered by Seedance 2.5.

[screen recording final video output] And this is the result. [pause] Notice the character hasn't drifted. The lighting and scene continuity carry through from the storyboard. This isn't a single disconnected clip it's an actual sequence that holds together, because every step before this one was building toward it.

That's really the point of Canvas. It's not a single-clip generator you roll the dice on. It's a full pipeline from planning to final output.

[SECTION 6: Broader Use Cases]

And to be clear [breathe] this isn't just for short dramas. The same workflow applies to short films, music videos, commercial-style ads, animation, and UGC-style content. Anywhere you need more than one shot to feel like the same world, Canvas is built for that.

[SECTION 7: Pricing]

Quick word on pricing, because I know you're wondering. [breathe] Buzzy runs on a credit system, and right now there's a 50% off sale on annual plans, so timing's decent if you're considering it.

Basic is around ten dollars a month billed annually two thousand credits, access to the core models, two videos running in parallel, watermark removed. Pro is nineteen a month four thousand credits, four parallel generations, and real face uploads unlocked, which matters if you're doing character-driven work. [pause] Above that there's Ultra and Infinite if you're producing at scale or working with a team.

For most people getting into Canvas, I'd start on Basic or Pro and scale up once you know how many credits your workflow actually needs.

[CTA / OUTRO]

So [breathe] if you're making AI short films, story-driven content, ads, or anything where more than one shot needs to hold together Buzzy Canvas is built around that exact problem. Script, characters, storyboard, and final video, all in one workspace, all connected.

[pause] That's the workflow, and from what I tested, it holds up shot to shot in a way most single-prompt tools don't.

Link's in the description, and there are free credits when you sign up, so you can try the workflow yourself before paying anything. [pause] I want to know what's the first AI video project you'd build with this? Script it out in the comments, I'm curious what people come up with.

And if you want more of these breakdowns, subscribe. [breathe] See you in the next one.
